# The Algebra and Topology of $\mathbb{R}^n$

## 1.1 Notes

1/10:
- Syllabus.
  - In his mind, homework is the main setting where learning takes place.
- We're going to be studying analysis, or calculus, on **manifolds** this quarter.
- **Manifold**: A "space" that looks like Euclidean space $\mathbb{R}^n$ locally.
  - The surfaces of a sphere and torus are common examples of 2-dimensional manifolds.
  - With regard to the above definition, think about how people in ancient times didn't think the Earth was a sphere because it looked like a plane locally.
- This class will look much like a calculus course, in that we first talk about limits, then differentiation, then integration, and culminating in the fundamental theory of calculus.
- Last quarter, we primarily developed linear algebra and basic topology on metric spaces.
  - Chapter 1 of Munkres (1991) is a review of what's needed from last quarter.
  - This is all basically continuity.
- Thus, we can start right up with differentiation.

## 1.2 The Algebra and Topology of $\mathbb{R}^n$

*From Munkres (1991).*

1/17:
- "In the first part of this book, $\mathbb{R}^n$ and its subspaces are the only vector spaces with which we shall be concerned. In later chapters, we shall deal with more general vector spaces" (Munkres, 1991, p. 2).
- **Inner product**: *Denoted by* $\langle \mathbf{x}, \mathbf{y} \rangle$.
- **Euclidean norm**: The following norm. *Denoted by* $\|\mathbf{x}\|$. *Given by*

$$\|\mathbf{x}\| = \sqrt{x_1^2 + \cdots + x_n^2}$$

- **Sup norm** (of $n$-tuples): The following norm. *Denoted by* $|\mathbf{x}|$. *Given by*

$$|\mathbf{x}| = \max\{|x_1|, \dots, |x_n|\}$$

- Note that the Euclidean norm and sup norm satisfy the inequalities

$$|\mathbf{x}| \leq \|\mathbf{x}\| \leq \sqrt{n}|\mathbf{x}|$$

  for all $\mathbf{x} \in \mathbb{R}^n$.

- **Sup norm** (of matrices): The following norm. *Denoted by* $\boldsymbol{|A|}$. *Given by*

$$|A| = \max\{|a_{ij}| : i \in [n],\ j \in [m]\}$$

- Theorem 1.3: If $A$ has size $n$ by $m$ and $B$ has size $m$ by $p$, then

$$|A \cdot B| \leq m|A|\,|B|$$

- **Echelon form**: *Also known as* **stairstep form**.
- **Transpose** (of $A$): *Denoted by* $\boldsymbol{A^{\mathrm{tr}}}$.
- Theorem 2.1: Let $A$ be an $n$-by-$m$ matrix. Any elementary row operation on $A$ may be carried out by premultiplying $A$ by the corresponding elementary matrix.
  - "We will use this result later on when we prove the change of variables theorem for a multiple integral" (Munkres, 1991, p. 12).
- **Determinant** (of $A$): *Denoted by* $\mathbf{det}\,\boldsymbol{A}$. *Not denoted by* $|A|$.
- **Determinant function**: A function that assigns to each $n$-by-$n$ matrix $A$ a real number denoted $\det A$ and satisfies the following axioms.
  1. If $B$ is the matrix obtained by exchanging any two rows of $A$, then $\det B = -\det A$.
  2. Given $i$, the function $\det A$ is linear as a function of the $i^{\text{th}}$ row alone.
  3. $\det I_n = 1$.
- Corollary 2.9: The determinant function is uniquely characterized by its three axioms.
- **$\boldsymbol{\epsilon}$-neighborhood** (of $x_0$): The following set, where $X$ is a metric space with metric $d$, $x_0 \in X$, and $\epsilon > 0$. *Also known as* **$\boldsymbol{\epsilon}$-neighborhood centered at $\boldsymbol{x_0}$**. *Denoted by* $\boldsymbol{U(x_0;\epsilon)}$. *Given by*

$$U(x_0;\epsilon) = \{x \mid d(x, x_0) < \epsilon\}$$

- **Topological property** (of $X$): A property of a metric space $X$ that depends only on the collection of open sets of $X$, rather than on the specific metric involved.
  - Examples include limits, continuity, and compactness.
- **Interior** (of $A \subset \mathbb{R}^n$): The union of all open sets of $\mathbb{R}^n$ that are contained in $A$. *Denoted by* $\mathbf{Int}\,\boldsymbol{A}$.
- **Exterior** (of $A \subset \mathbb{R}^n$): The union of all open sets of $\mathbb{R}^n$ that are disjoint from $A$. *Denoted by* $\mathbf{Ext}\,\boldsymbol{A}$.
- **Boundary** (of $A \subset \mathbb{R}^n$): The set of all points of $\mathbb{R}^n$ that are contained in neither $\operatorname{Int} A$ nor $\operatorname{Ext} A$. *Denoted by* $\mathbf{Bd}\,\boldsymbol{A}$.
  - $\mathbf{x} \in \operatorname{Bd} A$ iff every open set containing $\mathbf{x}$ intersects both $A$ and $\mathbb{R}^n \setminus A$.

# Chapter 2

# Differentiation

## 2.1 Notes

1/10:

- Since manifolds look like Euclidean spaces locally, we basically only need to study differentiation on Euclidean spaces.
- Set up: Let $U \subset \mathbb{R}^n$ be open, and $f : U \to \mathbb{R}^n$ be a function.
- Idea: The derivative of $f$ at some point $\mathbf{a} \in U$ is "the best linear approximation" to $f$ at $\mathbf{a}$.
- **Differentiable** (function $f$ at $\mathbf{a}$): A function $f$ for which there exists a linear transformation $A : \mathbb{R}^n \to \mathbb{R}^m$ such that
$$\lim_{\mathbf{h} \to \mathbf{0}} \frac{f(\mathbf{a}+\mathbf{h}) - f(\mathbf{a}) - A\mathbf{h}}{\|\mathbf{h}\|} = \mathbf{0}$$
- **Total derivative** (of $f$ at $\mathbf{a}$): The linear transformation $A$ corresponding to a differentiable function $f$. *Denoted by* $\boldsymbol{Df}(\mathbf{a})$.
- Questions to ask:
  1. When does the total derivative exist?
  2. When it does exist, can there be multiple?
  3. When it exists and is unique, how do I calculate it?
- Proposition: If $A, B$ are linear transformations that both satisfy the definition, then $A = B$.
  - We have
$$\lim_{\mathbf{h} \to \mathbf{0}} \frac{f(\mathbf{a}+\mathbf{h}) - f(\mathbf{a}) - A\mathbf{h}}{\|\mathbf{h}\|} = \mathbf{0} \qquad \lim_{\mathbf{h} \to \mathbf{0}} \frac{f(\mathbf{a}+\mathbf{h}) - f(\mathbf{a}) - B\mathbf{h}}{\|\mathbf{h}\|} = \mathbf{0}$$
  - It follows by subtracting the right equation above from the left one that
$$\lim_{\mathbf{h} \to \mathbf{0}} \frac{A\mathbf{h} - B\mathbf{h}}{\|\mathbf{h}\|} = \mathbf{0}$$
  - Apply linearity: For $\mathbf{v} \in \mathbb{R}^n$ and $t \in \mathbb{R}$, $t > 0$, we have
$$\frac{A(t\mathbf{v}) - B(t\mathbf{v})}{t} = A\mathbf{v} - B\mathbf{v}$$

- Therefore, since $t\mathbf{v} \to 0$ as $t \to 0$, we have by the above that

$$\begin{aligned}
\mathbf{0} &= \lim_{t\to 0} \frac{A(t\mathbf{v}) - B(t\mathbf{v})}{\|t\mathbf{v}\|} \\
&= \lim_{t\to 0} \frac{A\mathbf{v} - B\mathbf{v}}{\|\mathbf{v}\|} \\
\mathbf{0} \cdot \|\mathbf{v}\| &= \lim_{t\to 0} (A\mathbf{v} - B\mathbf{v}) \\
\mathbf{0} &= A\mathbf{v} - B\mathbf{v} \\
B\mathbf{v} &= A\mathbf{v}
\end{aligned}$$

- Example: Let $f : \mathbb{R}^n \to \mathbb{R}^m$ be linear, i.e., $f(\mathbf{v}) = A\mathbf{v}$ for some linear transformation $A$. Then for all $\mathbf{a} \in \mathbb{R}^n$, $Df(\mathbf{a}) = A$ is constant.
  - We have from the definition that

$$\begin{aligned}
\lim_{\mathbf{h}\to\mathbf{0}} \frac{f(\mathbf{a}+\mathbf{h}) - f(\mathbf{a}) - A\mathbf{h}}{\|\mathbf{h}\|} &= \lim_{\mathbf{h}\to\mathbf{0}} \frac{f(\mathbf{a}) + f(\mathbf{h}) - f(\mathbf{a}) - f(\mathbf{h})}{\|\mathbf{h}\|} \\
&= \lim_{\mathbf{h}\to\mathbf{0}} \frac{\mathbf{0}}{\|\mathbf{h}\|} \\
&= \mathbf{0}
\end{aligned}$$

- Theorem: If $f$ is differentiable at $\mathbf{a}$, then $f$ is continuous at $\mathbf{a}$.
  - By definition, there exists a linear transformation $A$ such that

$$\lim_{\mathbf{h}\to\mathbf{0}} \frac{f(\mathbf{a}+\mathbf{h}) - f(\mathbf{a}) - A\mathbf{h}}{\|\mathbf{h}\|} = \mathbf{0}$$

  - Additionally, we have that

$$f(\mathbf{a}+\mathbf{h}) = f(\mathbf{a}) + A\mathbf{h} + \|\mathbf{h}\| \left( \frac{f(\mathbf{a}+\mathbf{h}) - f(\mathbf{a}) - A\mathbf{h}}{\|\mathbf{h}\|} \right)$$

  - As $\mathbf{h} \to \mathbf{0}$, the right-hand side of the above equation goes to $f(\mathbf{a})$.
    - As a linear transformation, $A\mathbf{h} \to \mathbf{0}$ as $\mathbf{h} \to \mathbf{0}$.
    - Clearly $\|\mathbf{h}\| \to \mathbf{0}$ as $\mathbf{h} \to \mathbf{0}$.
    - And we have by definition that the last term goes to $\mathbf{0}$ as $\mathbf{h} \to \mathbf{0}$.
  - Therefore, $f$ is continuous at $\mathbf{a}$.
- Observation: A function $f : U \to \mathbb{R}^m$ is given by an $m$-tuple of functions $f_1 : U \to \mathbb{R}$ known as components. $f = (f_1, \dots, f_m)$.
- Proposition: $f$ is differentiable at $\mathbf{a} \in U$ iff each component function $f_i$ is differentiable at $\mathbf{a}$. In this case,

$$Df(\mathbf{a}) = (Df_1(\mathbf{a}), \dots, Df_m(\mathbf{a}))$$

  - We know that

$$\lim_{\mathbf{h}\to\mathbf{0}} \frac{f(\mathbf{a}+\mathbf{h}) - f(\mathbf{a}) - A\mathbf{h}}{\|\mathbf{h}\|} \in \mathbb{R}^m$$

  - Thus, the limit is zero iff the limit of each component is zero.
  - We have that the $i^{\text{th}}$ component of the vector on the left below is equal to the number on the right; we call the common value $L_i(\mathbf{h})$.

$$\left( \frac{f(\mathbf{a}+\mathbf{h}) - f(\mathbf{a}) - A\mathbf{h}}{\|\mathbf{h}\|} \right)_i = \frac{f_i(\mathbf{a}+\mathbf{h}) - f_i(\mathbf{a}) - (A\mathbf{h})_i}{\|\mathbf{h}\|}$$

- The upshot is that $f$ is differentiable at $\mathbf{a}$ iff $\lim_{\mathbf{h}\to\mathbf{0}} L_i(\mathbf{h}) = \mathbf{0}$ iff the linear transformation $\mathbf{h} \mapsto (A\mathbf{h})_i : \mathbb{R}^m \to \mathbb{R}$ is the total derivative of $f_i$.

- Now, each $f_i$ is a function of $n$ variables, i.e., $f_i(x_1, \dots, x_n)$ where $x_1, \dots, x_n$ are coordinates on $\mathbb{R}^n$.

1/12:
- **Partial derivative** (of $f$ wrt. $x_i$ at $\mathbf{a} \in U$): The following quantity. *Denoted by* $\boldsymbol{\partial f/\partial x_i}$. *Given by*

$$\frac{\partial f}{\partial x_i} = \lim_{h\to 0} \frac{f(a_1, \dots, a_{i-1}, a_i + h, a_{i+1}, \dots, a_n) - f(\mathbf{a})}{h}$$

  - The partial derivative is easy to calculate if you're good at calculating single-variable derivatives.

- Questions:
  1. If the partial derivatives all exist, does the total derivative also exist?
  2. If partial derivatives exist, is $f$ continuous?

- The answer is no to both — it's too weak a condition.
  - Counter example: Consider $f : \mathbb{R}^2 \to \mathbb{R}$ given by

$$f(x, y) = \begin{cases} \frac{x^2 y}{x^4 + y^4} & (x, y) \neq \mathbf{0} \\ 0 & (x, y) = \mathbf{0} \end{cases}$$

  - All partial derivatives exist at $(0, 0)$ but $f$ is not continuous at $(0, 0)$.
  - We'll consider this in the homework.

- Now we try taking derivatives in infinitely many directions, as opposed to just $n$ many.

- **Directional derivative** (of $f$ at $\mathbf{a}$ in the direction of $\mathbf{v} \in \mathbb{R}^n$): The following quantity. *Denoted by* $\boldsymbol{D_{\mathbf{v}} f(\mathbf{a})}$, $\boldsymbol{\partial f/\partial \mathbf{v}}$. *Given by*

$$D_{\mathbf{v}} f(\mathbf{a}) = \frac{\partial f}{\partial \mathbf{v}} = \lim_{h\to 0} \frac{f(\mathbf{a} + h\mathbf{v}) - f(\mathbf{a})}{h}$$

  - We always take $\|\mathbf{v}\| = 1$.
  - The partial derivative is just a directional derivative along the standard basis vectors. Alternatively, the directional derivative is just a generalization of the partial derivatives.

- This still isn't a strong enough condition — the above counterexample has all directional derivatives at $(0, 0)$ but still isn't continuous.

- Proposition: Suppose $f$ is differentiable at $\mathbf{a} \in U$. Then all directional derivatives of $f$ at $\mathbf{a}$ exist and for all $\mathbf{v} \in \mathbb{R}^n$,

$$\frac{\partial f}{\partial \mathbf{v}} = Df(\mathbf{a})(\mathbf{v})$$

  - The total derivative says that the derivative exists from all sequences of approach. We're just going to pick a particular vector direction of approach.
  - Mathematically, by the definition of the total derivative,

$$\begin{aligned} \mathbf{0} &= \lim_{h\to 0} \frac{f(\mathbf{a} + h\mathbf{v}) - f(\mathbf{a}) - Df(\mathbf{a})(h\mathbf{v})}{h} \\ &= \lim_{h\to 0} \frac{f(\mathbf{a} + h\mathbf{v}) - f(\mathbf{a})}{h} - Df(\mathbf{a})(\mathbf{v}) \\ Df(\mathbf{a})(\mathbf{v}) &= \frac{\partial f}{\partial \mathbf{v}} \end{aligned}$$

- A particular consequence is that
$$\frac{\partial f}{\partial x_i} = Df(\mathbf{a})(e_i)$$
  - But the total derivative, as a linear transformation, is completely defined by its behavior on the basis vectors.
  - Thus, it is defined by the $m$-by-$n$ matrix
$$Df(\mathbf{a}) = \left(\frac{\partial f_j}{\partial x_i}\right)_{\substack{1\le j\le m\\ 1\le i\le n}}$$
- **Jacobian matrix** (of $f$ at $\mathbf{a}$): The above matrix, representing the total derivative of $f$ at $\mathbf{a}$.
- Theorem: Suppose $f : U \to \mathbb{R}^m$ is a function on an open set $U \subset \mathbb{R}^n$. If all partial derivatives of $f$ exist and are continuous on $U$, then $f$ is differentiable on $U$.
  - Recall the mean value theorem (MVT): Suppose $g : [a, b] \to \mathbb{R}$ is a continuous function which is differentiable on $(a, b)$. Then there exists $c \in (a, b)$ such that $g'(c) = [g(b) - g(a)]/[b - a]$.
  - WLOG let $m = 1$ (if we prove this case, we can use the proposition relating $f$ to its components to prove the general case).
  - Rewrite
$$\begin{aligned} f(\mathbf{a}+\mathbf{h}) - f(\mathbf{a}) &= f(a_1+h_1, a_2+h_2, a_3+h_3, \ldots, a_n+h_n) - f(a_1, a_2+h_2, a_3+h_3, \ldots, a_n+h_n) \\ &\quad + f(a_1, a_2+h_2, a_3+h_3, \ldots, a_n+h_n) - f(a_1, a_2, a_3+h_3, \ldots, a_n+h_n) \\ &\quad + \cdots \\ &\quad + f(a_1, \ldots, a_{n-1}, a_n+h_n) - f(\mathbf{a}) \end{aligned}$$
    where $\mathbf{a} = (a_1, \ldots, a_n)$ and $\mathbf{h} = (h_1, \ldots, h_n)$.
  - Apply the MVT to each term to get
$$f(a_1, \ldots, a_i+h_i, \ldots, a_n+h_n) - f(a_1, \ldots, a_i, \ldots, a_n+h_n) = h_i \frac{\partial f}{\partial x_i}(a_1, \ldots, c_i(\mathbf{h}), \ldots, a_n+h_n)$$
    for some $c_i(\mathbf{h}) \in (a_i, a_i+h_i) \cup (a_i+h_i, a_i)$.
  - Now let $A$ be the Jacobian matrix of $f$ at $\mathbf{a}$.
  - WTS:
$$\lim_{\mathbf{h}\to\mathbf{0}} \frac{f(\mathbf{a}+\mathbf{h}) - f(\mathbf{a}) - A\mathbf{h}}{\|\mathbf{h}\|} = \mathbf{0}$$
  - We have
$$f(\mathbf{a}+\mathbf{h}) - f(\mathbf{a}) = \sum_{i=1}^n h_i \frac{\partial f}{\partial x_i}(a_1, \ldots, c_i(\mathbf{h}), \ldots, a_n+h_n)$$
  - Let $\pi_i : \mathbb{R}^n \to \mathbb{R}^n$ be the linear map $(x_1, \ldots, x_n) \mapsto (0, \ldots, x_i, \ldots, 0)$. Clearly, $\mathbf{x} = \sum_{i=1}^n \pi_i \mathbf{x}$.
  - Thus, $A\mathbf{h} = \sum_{i=1}^n A\pi_i\mathbf{h}$ and $A\pi_i\mathbf{h} = \frac{\partial f}{\partial x_i}(\mathbf{a}) \cdot h_i$.
  - Applying, we have
$$\begin{aligned} \frac{f(\mathbf{a}+\mathbf{h}) - f(\mathbf{a}) - A\mathbf{h}}{\|\mathbf{h}\|} &= \sum_{i=1}^n \frac{1}{\|\mathbf{h}\|}\left(h_i \frac{\partial f}{\partial x_i}(a_1, \ldots, a_{i-1}, c_i(\mathbf{h}), a_{i+1}+h_{i+1}, \ldots, a_n+h_n) - \frac{\partial f}{\partial x_i}(\mathbf{a}) \cdot h_i\right) \\ &= \sum_{i=1}^n \frac{h_i}{\|\mathbf{h}\|}\left(\frac{\partial f}{\partial x_i}(a_1, \ldots, a_{i-1}, c_i(\mathbf{h}), a_{i+1}+h_{i+1}, \ldots, a_n+h_n) - \frac{\partial f}{\partial x_i}(\mathbf{a})\right) \end{aligned}$$
  - We know that $-1 \le h_i/\|\mathbf{h}\| \le 1$, so we need only show that the difference above goes to zero as $\mathbf{h} \to \mathbf{0}$. But we know this by the continuity of the partial derivatives.

- Note that this theorem gives a sufficient condition but not a necessary condition for $f$ to be differentiable.

1/14:
- Theorem (Chain Rule): Suppose $f : U \to \mathbb{R}^m$ and $g : V \to \mathbb{R}^p$ are functions defined on open sets $U \subset \mathbb{R}^n$, $V \subset \mathbb{R}^m$ with $f(U) \subset V$. Suppose that $f$ is differentiable at $\mathbf{a} \in U$ and $g$ is differentiable at $\mathbf{b} = f(\mathbf{a}) \in V$. Then the composite function $g \circ f : U \to \mathbb{R}^p$ is differentiable at $\mathbf{a}$ and $D(g \circ f)(\mathbf{a}) = Dg(\mathbf{b}) \circ Df(\mathbf{a}) : \mathbb{R}^n \to \mathbb{R}^p$.
  - Note that $f : U \to \mathbb{R}^m$ is differentiable at $\mathbf{a} \in U$ with derivative $A$ iff $f(\mathbf{a}+\mathbf{h}) = f(\mathbf{a}) + A\mathbf{h} + \tilde{f}(\mathbf{h})$ such that
  $$\lim_{\mathbf{h}\to\mathbf{0}} \frac{\tilde{f}(\mathbf{h})}{\|\mathbf{h}\|} = \mathbf{0}$$
  where $\tilde{f}$ is an error function.
    - We're just rearranging terms here.
    - If you like, $\tilde{f}$ is the numerator from the definition of the total derivative.
  - Let $A = Df(\mathbf{a})$, $B = Dg(\mathbf{b})$. Then
  $$f(\mathbf{a}+\mathbf{h}) = f(\mathbf{a}) + A\mathbf{h} + \tilde{f}(\mathbf{h})$$
  so
  $$\begin{aligned}(g \circ f)(\mathbf{a}+\mathbf{h}) &= g(f(\mathbf{a}+\mathbf{h}))\\ &= g(f(\mathbf{a})) + A\mathbf{h} + \tilde{f}(\mathbf{h})\\ &= g(f(\mathbf{a})) + B(A\mathbf{h} + \tilde{f}(\mathbf{h})) + \tilde{g}(A\mathbf{h} + \tilde{f}(\mathbf{h}))\\ &= g(f(\mathbf{a})) + BA\mathbf{h} + B\tilde{f}(\mathbf{h}) + \tilde{g}(A\mathbf{h} + \tilde{f}(\mathbf{h}))\end{aligned}$$
  - WTS: $\lim_{\mathbf{h}\to\mathbf{0}}[B\tilde{f}(\mathbf{h}) + \tilde{g}(A\mathbf{h} + \tilde{f}(\mathbf{h}))]/\|\mathbf{h}\| = \mathbf{0}$.
  - For the first half of the fraction,
  $$\frac{B\tilde{f}(\mathbf{h})}{\|\mathbf{h}\|} = B\left(\frac{\tilde{f}(\mathbf{h})}{\|\mathbf{h}\|}\right) \to \mathbf{0}$$
  as $\mathbf{h} \to \mathbf{0}$ since the argument goes to $\mathbf{0}$ as $\mathbf{h} \to \mathbf{0}$ and $B$ is a linear transformation (in particular, $B(\mathbf{0}) = \mathbf{0}$).
  - For the second half of the fraction,
  $$\lim_{\mathbf{h}\to\mathbf{0}} \frac{\tilde{g}(A\mathbf{h} + \tilde{f}(\mathbf{h}))}{\|\mathbf{h}\|} = \lim_{\mathbf{h}\to\mathbf{0}} \frac{\tilde{g}(A\mathbf{h} + \tilde{f}(\mathbf{h}))}{\left\|A\mathbf{h} + \tilde{f}(\mathbf{h})\right\|} \cdot \frac{\left\|A\mathbf{h} + \tilde{f}(\mathbf{h})\right\|}{\|\mathbf{h}\|}$$
    - The left fraction on the right side of the equality goes to zero as $\mathbf{h} \to \mathbf{0}$ by the definition of $\tilde{g}$.
    - The right fraction on the right side of the equality is bounded since
    $$\frac{\left\|A\mathbf{h} + \tilde{f}(\mathbf{h})\right\|}{\|\mathbf{h}\|} \leq \frac{\|A\mathbf{h}\|}{\|\mathbf{h}\|} + \frac{\left\|\tilde{f}(\mathbf{h})\right\|}{\|\mathbf{h}\|} \leq \|A\| + \frac{\left\|\tilde{f}(\mathbf{h})\right\|}{\|\mathbf{h}\|}$$
    where $\|A\|$ is the operator norm and $\left\|\tilde{f}(\mathbf{h})\right\|/\|\mathbf{h}\| \to 0$ as $\mathbf{h} \to \mathbf{0}$ by the definition of $\tilde{f}$.
    - Thus, the second half of the fraction goes to zero as well.
- Theorem: Let $U \subset \mathbb{R}^m$ be an open subset.

1. Suppose $f, g : U \to \mathbb{R}^m$ are functions that are differentiable at $\mathbf{a} \in U$. Then $f + g$ is also differentiable at $\mathbf{a} \in U$ and
$$D(f+g)(\mathbf{a}) = Df(\mathbf{a}) + Dg(\mathbf{a})$$
2. Suppose $f, g : U \to \mathbb{R}$ are both differentiable at $\mathbf{a} \in U$. Then $f \cdot g$ is also differentiable at $\mathbf{a}$, and
$$D(f \cdot g)(\mathbf{a}) = Df(\mathbf{a}) \cdot g(\mathbf{a}) + f(\mathbf{a}) \cdot Dg(\mathbf{a})$$
3. Suppose $f : U \to \mathbb{R}$ is differentiable at $\mathbf{a} \in U$ and $f(\mathbf{a}) \neq 0$. Then $1/f$ is differentiable at $\mathbf{a} \in U$ and
$$D(1/f)(\mathbf{a}) = -\frac{Df(\mathbf{a})}{f(\mathbf{a})^2}$$

– Proof of 1: Consider the functions $F : U \to \mathbb{R}^{2m}$ and $G : \mathbb{R}^m \times \mathbb{R}^m \to \mathbb{R}^m$ defined by
$$F(\mathbf{x}) = (f(\mathbf{x}), g(\mathbf{x})) \qquad\qquad G(\mathbf{y}, \mathbf{z}) = \mathbf{y} + \mathbf{z}$$
so that
$$f + g = G \circ F$$
  - $F$ is differentiable because its components are differentiable.
  - $G$ is differentiable because it's linear. This also implies that $DG(\mathbf{x}) = G$.
  - Apply the chain rule to learn that $G \circ F$ is differentiable with derivative
$$\begin{aligned} D(f+g)(\mathbf{a}) &= D(G \circ F)(\mathbf{a}) \\ &= DG(F(\mathbf{a})) \circ DF(\mathbf{a}) \\ &= G(DF(\mathbf{a})) \\ &= G(Df(\mathbf{a}), Dg(\mathbf{a})) \\ &= Df(\mathbf{a}) + Dg(\mathbf{a}) \end{aligned}$$

– Prove the others the same way.

- Theorem (Mean Value Theorem): Suppose $f : U \to \mathbb{R}$ is differentiable for all $\mathbf{a} \in U$ and that $U$ contains the line segment joining $\mathbf{a}, \mathbf{a} + \mathbf{h} \in U$. Then there exists $t_0 \in (0, 1)$ such that
$$f(\mathbf{a} + \mathbf{h}) - f(\mathbf{a}) = Df(\mathbf{a} + t_0\mathbf{h})(\mathbf{h})$$
  – Define $\phi(t) = f(\mathbf{a} + t\mathbf{h})$ for $t \in [0, 1]$.
  – Apply the usual MVT to $\phi$ to learn that there exists $t_0 \in (0, 1)$ such that $\phi(1) - \phi(0) = \phi'(t_0)$.
  – Then using the chain rule, $\phi'(t_0) = Df(\mathbf{a} + t_0\mathbf{h})(\mathbf{h})$.
- We now discuss higher order derivatives.
- **Differentiable** ($f$ on $U$): A function $f$ that is differentiable at every $\mathbf{a} \in U$.
- If $f$ is differentiable on $U$, then the total derivative gives a map $Df : U \to \mathcal{L}(\mathbb{R}^n, \mathbb{R}^m)$.
  – Note that $\mathcal{L}(\mathbb{R}^n, \mathbb{R}^m)$ is isomorphic to the set of all $m$-by-$n$ matrices, and $\mathbb{R}^{mn}$.
- We can ask for $Df$ to itself be differentiable. We define
$$D^2 f = D(Df)$$
if it exists and, more generally,
$$D^k f = D(D^{k-1} f)$$
- **Class $\boldsymbol{C^k}$** (function): A function $f : U \to \mathbb{R}^m$ for which $Df, \dots, D^k f$ all exist and are continuous on $U$.

  - Note that we technically need only require that $D^k f$ exist, as this implies the existence of $Df, \dots, D^{k-1}f$.
  - A function $f : U \to \mathbb{R}^m$ is of class $C^k$ iff all partial derivatives $\partial f / \partial x_i : U \to \mathbb{R}^m$ exist and are of class $C^{k-1}$ (this follows from the theorem relating partial derivatives and differentiability).
- **Smooth** (function): A function of class $C^\infty$.
